

An automatic tool  
(black box) to compute  
a reaction mechanism  
does not exist

computational  
strategy  
needed

A few fundamental concepts:

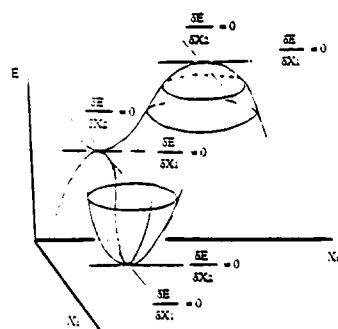

The concept of potential energy surface (PES) associated with a chemical reaction

Relevant points on a PES  
All the relevant points on a PES are stationary points

First Derivatives of the Energy with respect to nuclear coordinates (forces) are zero:  
 $\frac{\partial E}{\partial X_i} = 0 \quad (i = 1, 2, \dots, 3N-6)$

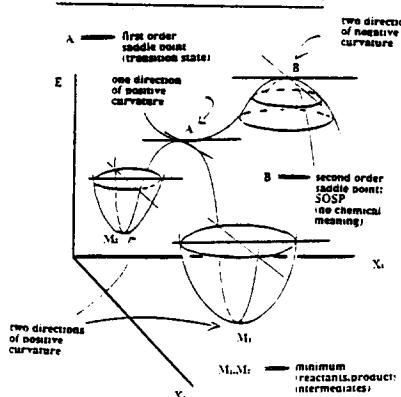

In topology stationary points are known as critical points

**Important Statement:**

Not all the critical points on a PES have chemical meaning

Consequently, after having found a critical point on a PES, you must also determine very carefully its nature

The nature of a critical point can be found easily if one can compute the force constant matrix with respect to the nuclear coordinates

The force constant for coordinate  $X_i$

$$\frac{\partial^2 E}{\partial X_i^2} \quad (\text{Second Derivative of the energy})$$

A 3-Dimensional case :  $E = E(X_1, X_2)$

The full second energy derivative matrix (Hessian) is required. The corresponding eigenvalues must be computed

$$\begin{matrix} \frac{\partial^2 E}{\partial X_1^2} & \frac{\partial^2 E}{\partial X_1 \partial X_2} \\ \frac{\partial^2 E}{\partial X_2 \partial X_1} & \frac{\partial^2 E}{\partial X_2^2} \end{matrix}$$

HESSIAN MATRIX

compute the corresponding eigenvalues

2 positive Eigenvalues

1 positive eig.  
1 negative eig.

2 negative eigenvalues

Minimum (Reactants, Products, Intermediates)

First Order Saddle Point (Transition State)

Maximum or Second Order Saddle Point (Sosp) (no chemical meaning)

The computational strategy which is employed is completely general

In principle you can get a complete 'a priori' analysis of the PES

In practice a too large number of computations is required to do that

This makes a full 'a priori' analysis too expensive for reactions of chemical interest

Consequently — in a 'routine' investigation of a chemical reaction it is convenient to perform the search for the various critical points (and the optimization of the corresponding geometrical structures) in some restricted areas of the Pes

A 2 Dimensional case  $E = E(X)$  Trivial solution

compute  $\frac{\partial^2 E}{\partial X^2}$

$$\frac{\partial^2 E}{\partial X^2} > 0 \rightarrow \text{Min.} \quad \frac{\partial^2 E}{\partial X^2} < 0 \rightarrow \text{Max.}$$

3-dimensional case

Easy to extend to the n-dimensional case  
 $n = 3N - 5$

evaluation of the  $n \times n$  (force constant matrix)

n eigenvalues

All eigenvalues are positive

only one eigenvalue is negative

P eigenvalues are negative

Minimum

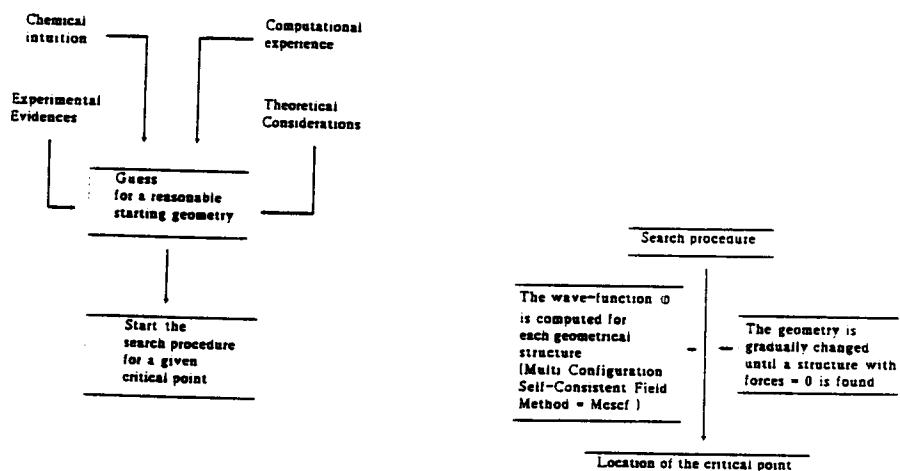

First order saddle point

A saddle point of order P

T.S.

No chemically Meaning

Factors which allow to choose the important restricted areas of the PES and to guess reasonable starting geometries for the critical points

#### QUANTUM MECHANICAL METHOD USED

MC-SCF (multi-configuration self-consistent field)

$$\Psi = \sum_i C_i \Psi_i$$

CSF (configuration state functions)

- ☰ virtual orbitals (unoccupied)
- ☰ active orbitals (variable occupancy)
- ☰ core orbitals (doubly occupied)

#### CAS (complete active space)

all possible configurations arising from the valence space

MC-SCF → Non-dynamic correlation energy (structure dependent)

Good description in the transition regions

MCSCF/MP2 (Single computations on geometries optimized at the mc-scf level) → Dynamic correlation energy

Very important for the computation of activation energies

#### CYCLOADDITION REACTION BETWEEN KETENE + ETHYLENE

Experimental Interest: Prototype Reaction for an important class of Reactions

#### CUMULENES - OLEFINS

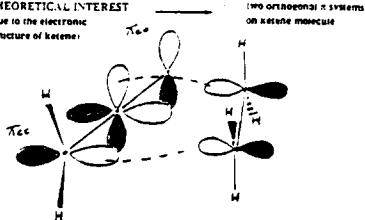

An important synthetic tool to obtain cyclic compounds

#### Basis sets

Minimal basis set (sto-3g) for exploratory work

Extended basis sets for an accurate computation of geometries and energies

THEORETICAL INTEREST  
due to the electronic  
structure of ketene

Simple MO concept  
suggests:

Possibility for a supra-antarctic  
attack (suprafacial approach  
for ethylene, antarafacial  
approach for ketene)

The most popular hypothesis  
in the mechanism of this  
reaction

The possibility has never  
been tested quantitatively

In agreement with experimental  
data (kinetic and stereochemical)  
evidence which suggests a concerted  
mechanism.

THE STRATEGY WHICH HAS BEEN  
USED TO STUDY THE REACTION  
OF KETENE + ETHYLENE IS BASED  
ON ANALOGOUS CYCLOADDITION  
REACTIONS

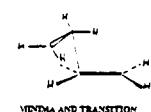

STRATEGY: KETENE

FORMALDEHYDE + FORMALDEHYDE

CRITICAL POINTS ON THE PES

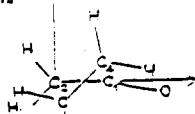

MINIMA AND TRANSITION STATE OF TRANS APPROACH

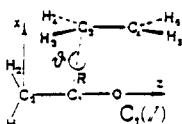

MINIMA AND TRANSITION STATE OF GAUCHE APPROACH

APPROACHING DIRECTIONS

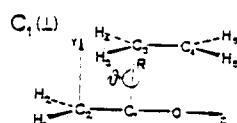

(a) supra-antarctic

(b) THE APPROACHING DIRECTION LIES IN THE  
PLANE OF THE KETENE MOLECULE

(c) THE APPROACHING DIRECTION IS PERPENDICULAR  
TO THE PLANE OF KETENE MOLECULE

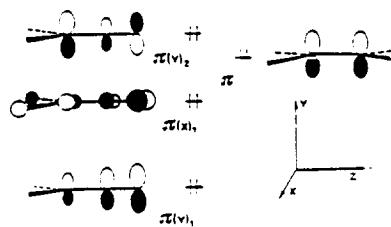

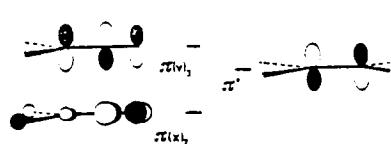

IN BOTH (b) AND (c) CASES THE ETHYLENE MOLECULE CAN  
ROTATE AROUND THE DIRECTION R. IN THIS WAY ALSO THE  
POSSIBILITY OF A GAUCHE ATTACK IS TAKEN INTO ACCOUNT.

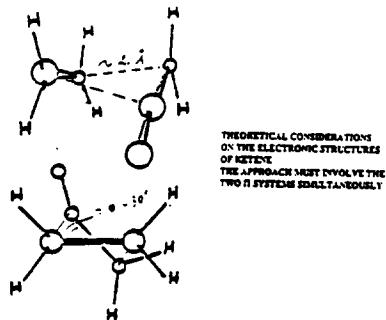

CRITICAL POINTS CORRESPONDING  
TO SUPRA-SUPRA APPROACH

CRITICAL POINTS CORRESPONDING  
TO SUPRA-ANTARCTIC APPROACH

APPROACHING DIRECTIONS

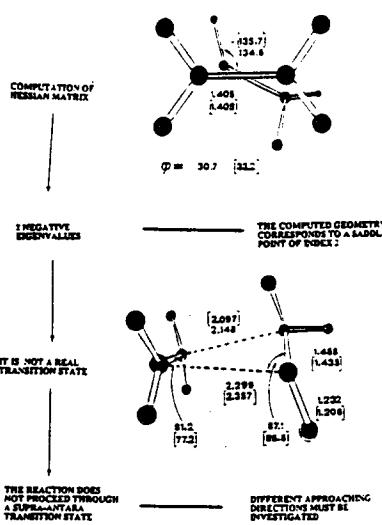

HYPOTHESIS FOR THE STARTING GEOMETRY  
ASSOCIATED WITH THE SUPRA-ANTARA ATTACK

THE COMPUTATIONAL EXPERIENCE ON  
SIMILAR REACTIONS (ETYLENE -  
ETYLENE) CAN SUGGEST REASONABLE  
STARTING VALUES FOR THE APPROACHING  
DISTANCE AND THE Φ ANGLE.

Supra-antara SOSP

Φ = 30.2 [312]

COMPUTATION OF HESSIAN MATRIX

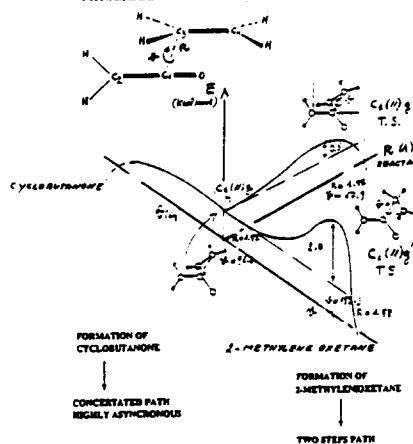

THE COMPUTED GEOMETRY CORRESPONDS TO A SADDLE POINT OF INDEX 2

IT IS NOT A REAL TRANSITION STATE

THE REACTION DOES NOT PROCEED THROUGH A SUPRA-ANTARA TRANSITION STATE

DIFFERENT APPROACHING DIRECTIONS MUST BE INVESTIGATED

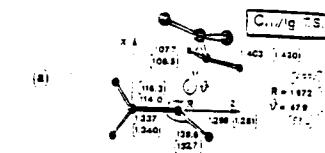

PARALLEL APPROACH → C1//I

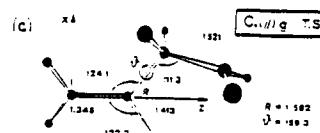

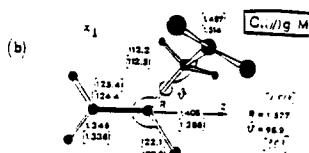

FORMATION OF CYCLOBUTANE  
CONCENTRATED PATH  
HIGHLY ASYCHRONOUS

FORMATION OF  
2-METHYLENE BUTANE  
TWO STEPS PATH

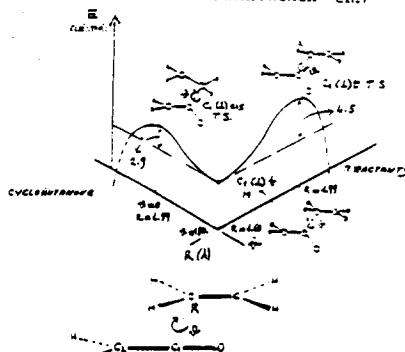

OPTIMUM GEOMETRICAL PARAMETERS  
OBTAINED FOR THE CRITICAL POINTS  
ASSOCIATED WITH THE C1//I APPROACH

BIRADICAL STRUCTURES

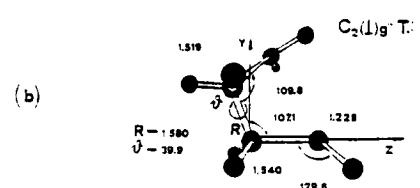

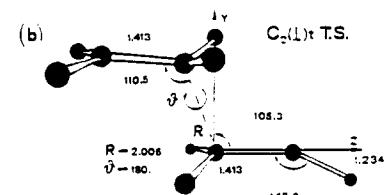

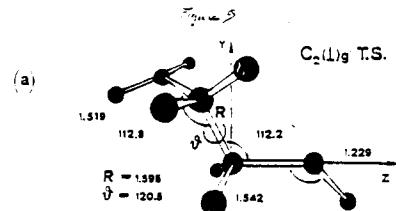

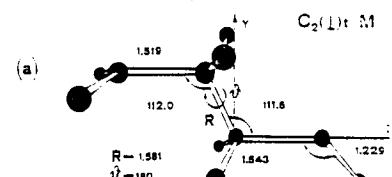

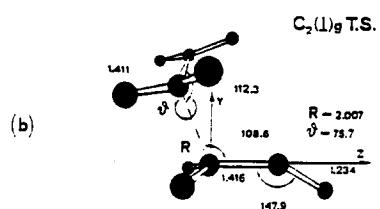

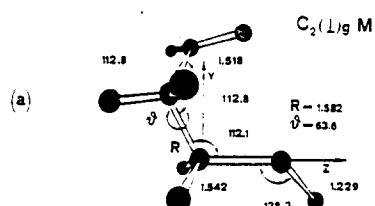

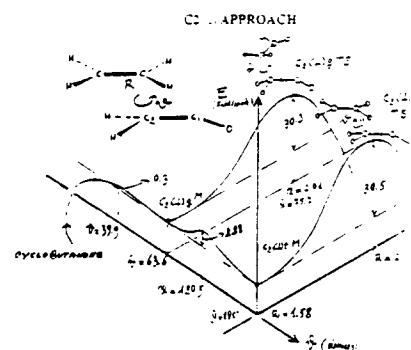

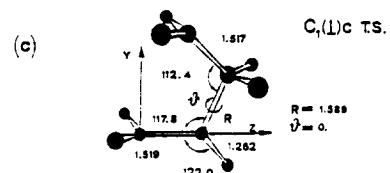

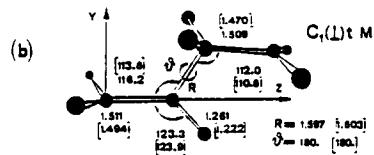

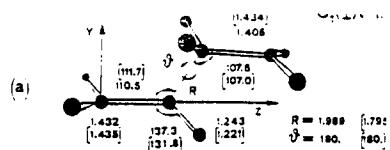

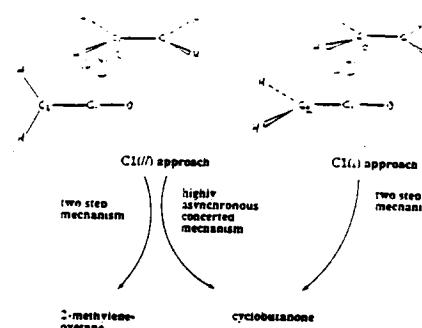

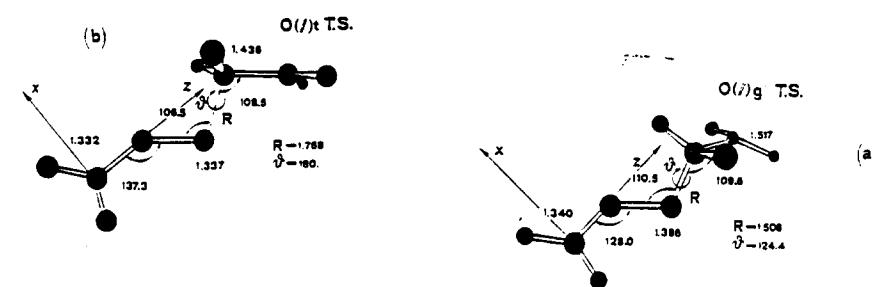

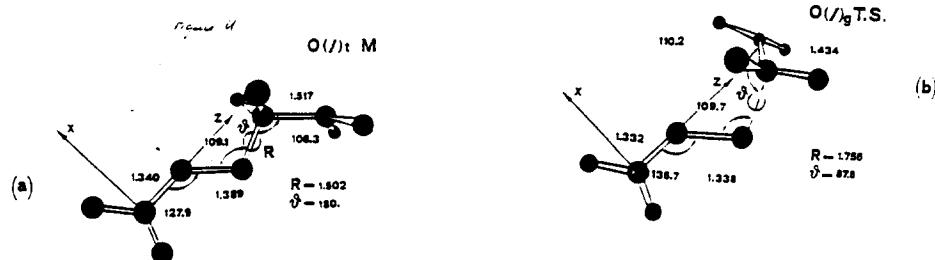

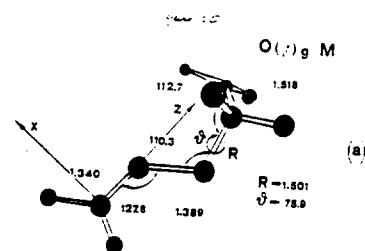

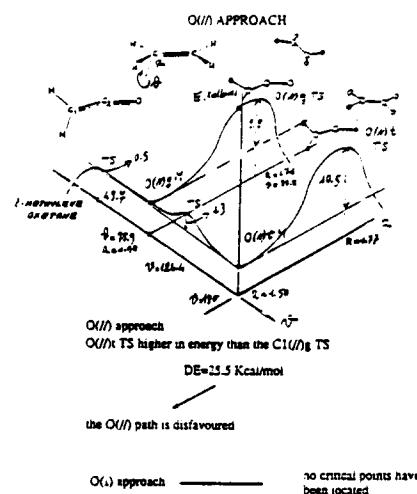

PERPENDICULAR APPROACH C1//I

C1/I//TS AND C1/I/g TS  
WITH ALMOST THE SAME  
ENERGIES

C1/I//TS ONLY  
SLIGHTLY DISFAVOURABLE:  
(-0.5 Kcal/mole)

**Notes:**

- 2-methyloxetane:** The C1(H) and C1(H)<sub>2</sub> paths are energetically very close.
- Cyclobutanone:** C1(H) slightly favoured with respect to C1(H)<sub>2</sub>.

**Concerted character of the C1(H) mechanism:** In agreement with the experimental evidences.

**Stereospecific reactions:** Stereospecific reactions.

**Concerted process:** Concerted process.

Possibility for a two-step mechanism

It can explain the results obtained in a few cases in the presence of large substituents

Stereospecificity is lost

A hint for a two-step mechanism

The C2(i) and O(i) pairs (two-step) are energetically disfavoured

A supra-anisic reaction path does not exist

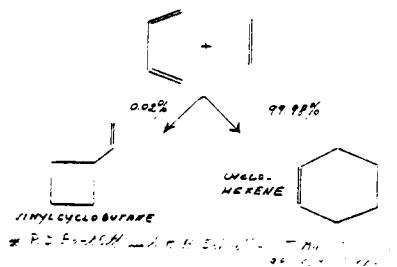

SOSP

### AN MCSCF STUDY OF THE DIELS-ALDER REACTION BETWEEN ETHYLENE AND BUTADIENE

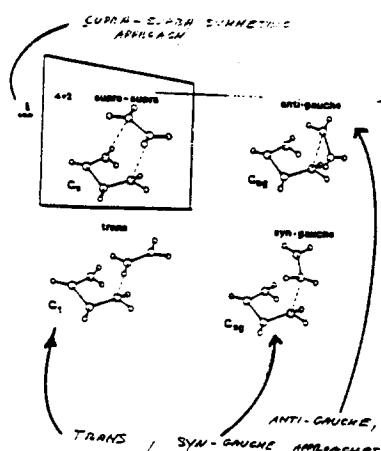

F. Goriely, F. Cetini and A. M. Della Dipartimento di Chimica "G. Ciamician" dell'Università di Bologna  
M. B. Rose Department of Chemistry, King's College of London

A LARGE NUMBER OF EXPERIMENTAL AND THEORETICAL STUDIES HAS BEEN PERFORMED ON THIS REACTION

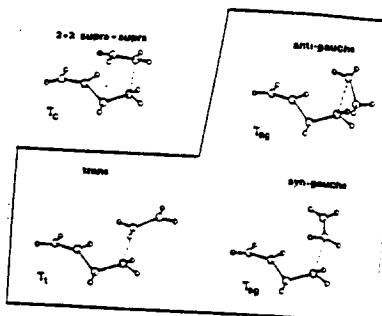

EXPERIMENTAL RESULTS OBTAINED BY BARTLETT<sup>1</sup> (1970) SHOW THAT THE PRODUCTS OF THE REACTION ARE:

- ② THE REACTION PATHS WHICH HAVE BEEN INVESTIGATED ARE ASSOCIATED WITH THE FOLLOWING APPROACHES:

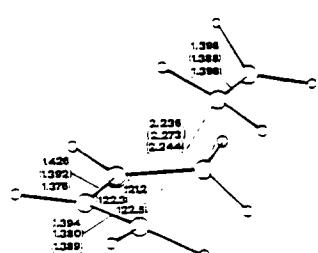

To understand the influence of the stereochemistry on the reactivity of the Diels-Alder reaction, both *trans*-approaches have been studied also for *trans*-butadiene, where the only product can be vinylcyclobutane. In this case, the reaction has been realized.

Potential Energy Surface for the Attack of Ethylene on *Cis* Butadiene. Three Critical Points

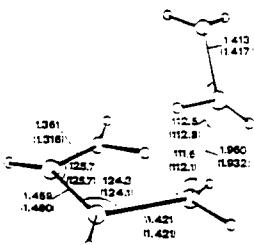

- 1) A critical point of  $C_2$  symmetry corresponding to concerted synchronous approach

Transition Structure

Hessian matrix with only one negative eigenvalue.  
Direction of negative curvature corresponding to approaching distance between the two molecules.

2) A critical point corresponding to a syn-gauche approach (denoted as  $C_{sg}$ )

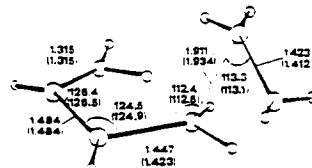

Minimum

Hessian matrix with only positive eigenvalues

This structure lies 2.2 Kcal/mol higher in energy than  $C_s$  transition structure

Closure to cyclohexene without almost any barrier

3) A critical point corresponding to an anti-gauche approach (denoted as  $C_{ag}$ )

minimum

Hessian matrix with only positive eigenvalues

This structure lies 5.6 Kcal/mol higher in energy than the  $C_s$  transition structure

Closure to vinyl-cyclobutane involves a transition structure of conformational type with a barrier of 5.2 Kcal/mol.

#### Attack of Ethylene on Cis Butadiene

Three different reaction paths
